Discuss the following. Document your answers and specific plans.

Scope

- What are the main areas of scope for your product that are still unclear?
    - What game elements are in the project
    - How exactly the task inputting and checking would work
    - What in-game rewards are granted
    - The reward to task completion ratio
    - How many options per element are available
- What will you do this week to drive closure on these questions?
    - We need to conduct research into implementing game elements into a functional software, to ensure that we are defining a clear scope for the game elements of the project.
    - Research game design and what makes games appealing to users
    - Ask ADHD individuals what motivates them in games
    -

End Users

- Where can you find end users that are not part of your team, immediate friend group or family?
    - Ask in our ECE class piazzas if suitable students would be interested in interviewing.
    - Go onto Reddit to seek out potential beta testers.
    -
- What is your plan for engaging these users to develop software requirements?
    - We will create surveys asking questions on the different aspects of our app. We will update them through our development process to gather continual feedback.
    - We will interview possible users

Requirements Brainstorming

- Review the MoSCow Method briefly.
- When will you schedule this brainstorming activity? Make a plan now.
    - We will meet on Wednesday at 2pm virtually to work through this brainstorming activity.

We are using the 9 stakeholders identified in the project proposal.

Must Haves:

- RQ-01: This project should take user input in the form of text to create events and tasks, which will be added to the user's calendar.
- RQ-02: This project should remind the user through OS notifications and emails of any events or tasks that are approaching, with frequency set by the user's preference.
- RQ-03: This project should allow users to spend in-game currency to purchase customization items, backgrounds, avatar frames, and more.
- RQ-04: This project should securely store user tasks and personal information on a cloud database system, which can be viewed by the user from within the application.
- RQ-05: This project should accept user login information and verify that they have an existing account with a matching username and password. Only by entering a valid username and password will the corresponding user's information be shared. The user only has to enter a password once if they choose to save their login information.
- RQ-06: The user should have the ability to mark off events (things that are happening) versus tasks (things that they need to do).
- RQ-07: Should accept uploads of brightspace and similar calendars, and automatically populate fields with task data.
- Documentation for both users and developers
- Instructions for users so that they can use functions that they may not fully understand
- Some background music
- Not possible to have multiple accounts linked to the same email/username
-

Should Haves:
- Customization feature beyond just customizing calendar
- Pulling info automatically from bright space and similar apps with minimal user input
- A complex password

Could Haves:
- RNG
- Local App (with automatic cloud updates when available)
-

Won't Haves:
- no pay to win
- Multi player
- Focus feature
- Features that can take up a lot of time

Reflection:
This process helped us figure out exactly what we wanted the application to do at a bare minimum. This helped us develop more exact specifications of what technology we would need. We learned how much more specific we needed to be and how our initial vagueness would have been harmful once we started to actually develop the website. The prioritization was definitely the most helpful portion of this process.
